

CODE BANKING USING THE KEIL 8051 TOOLS

Relevant Devices

This application note applies to the following devices: C8051F120, C8051F121, C8051F122, C8051F123, C8051F124, C8051F125, C8051F126, and C8051F127.

Introduction

The 8051 architecture supports a 64KB linear program memory space. Devices that have more than 64KB of program memory implement a code banking scheme to surmount this 64KB limit. This application note discusses software project management techniques and provides example applications that use code banking.

Key Points

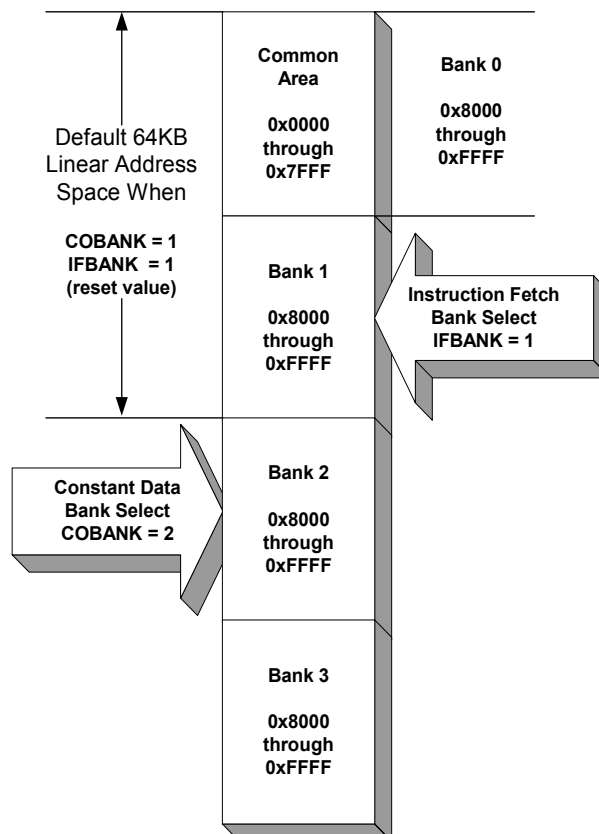

- Projects requiring less than 64KB of FLASH can leave the PSBANK register at its default setting which provides a 64KB linear address space.
- Code banked projects with more than 64KB of program code typically contain multiple source files, one or more for each code bank.

Code Banking Overview

The C8051F12x family of devices has 128KB of on-chip FLASH, divided into 4 physical 32KB banks. This program memory space can be used to

hold executable code or constant data. Figure 1 shows the code banking model implemented by these devices. Instruction fetch operations (normal code execution) are handled independently of constant data operations (MOVC instructions, and MOVX instructions when used for writing to FLASH). Each type of operation has its own bank select bits that may select any of the 4 banks as shown in Figure 1. All code bank switching is handled at the device level by writing to the PSBANK register. The COBANK and IFBANK bits in this register control switching for constant code accesses and instruction fetches, respectively. For more information on code bank switching, please refer to the C8051F12x datasheet.

Figure 1. C8051F12x Code Banking Model

For projects that require more than 64KB of code space or non-volatile data space, the user has the option of manually handling the bank switching in software or setting up a code- banked project. Both methods are discussed in this note.

User-Managed Bank Switching for Data Intensive Projects

User-managed bank switching is useful for projects that have less than 64KB of executable code but need to store large amounts of data in FLASH. In this situation, the Common area and Bank 1 are used for program memory while Bank 2 and Bank 3 are used for data storage. The project does not need to be set up for code banking.

The following data logging example shows how bank switching can be managed in application software.

Example 1: Data Logging Application

This application uses a 22.1184 MHz crystal oscillator to implement a software real-time clock (RTC). PCA0, configured to count Timer 0 overflows, generates an interrupt once every second. The interrupt handler records the current time and device temperature in a non-volatile log in FLASH.

The 112,640 byte log cycles through all 4 code banks recording time and temperature. Each data record has 6 fields as shown in Figure 2. The log is capable of storing 14080 records over a time period of 3.9 hours. Once the log is full, it continues log-

ging at the beginning of log, erasing the FLASH page with the oldest data as it progresses.

Managing the Instruction Fetch Bank Select

Since this application uses less than 32KB of FLASH for program code, there will be no instruction fetches from the 0x8000 to 0xFFFF memory space. This makes the value of IFBANK a “don’t care”. However, if an application uses between 32KB and 64KB of FLASH for program code, IFBANK should be left at its reset value, targeting Bank 1.

Advancing Through the Code Banks

This application reserves the first 16KB of FLASH in the Common area for program code. The log starts at address 0x4000 in the Common area and

Figure 2. Log Record Structure

ends at location 0xF7FF in Bank 3 as shown in Figure 3.

After storing a record in the log, the FLASH write pointer is advanced to the next record and checked for code bank boundaries. There are three possible boundary conditions to consider when adjusting the

FLASH write pointer. These cases are outlined in Table 1.

Preserving the PSBANK Register in Functions and Interrupt Service Routines

A program must preserve and restore the value of the PSBANK register in every function and interrupt service routine that switches code banks.

Choosing Log Record Size

Example 1 only writes entire records to FLASH. If the record size is a power of 2 and the log starts at the beginning of a FLASH page, then all records will be contained within one of the code banks. If a record can cross a bank boundary, then bounds checking must be performed after every byte write.

Keeping Accurate Time

This application keeps track of time by implementing an interrupt driven real-time clock. With SYSCCLK at 49.7664 MHZ, Timer 0 in mode 2 overflows exactly 4050 times every second when clocked by SYSCCLK/48. PCA Module 0 is configured in “Software Timer Mode” to count Timer 0 overflows and generate an interrupt every second.

Figure 3. FLASH Memory Map for Example 1

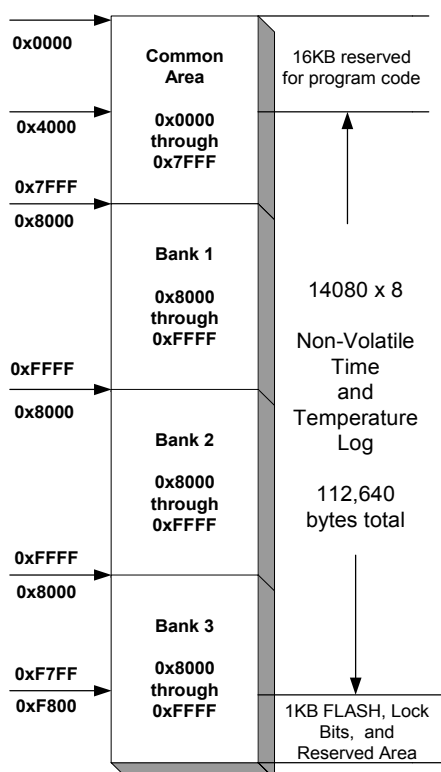

Table 1. FLASH Write Pointer Boundary Conditions

Condition	How to Detect	Typical Action
FLASH write pointer reaches the end of the Common area.	FLASH write pointer will point to location 0x8000.	No action is necessary if COBANK is always set to Bank 1 whenever the pointer is moved to the beginning of the log.
FLASH write pointer reaches the end of Bank 1 or Bank 2.	FLASH write pointer will point to location 0x0000.	FLASH write pointer should be set to 0x8000 and COBANK should be incremented.
FLASH write pointer reaches the end of the log.	FLASH write pointer will point to location 0xF800 and Bank 3 will be selected by COBANK.	FLASH write pointer should be reset to the first location in the log (0x4000) and COBANK should select Bank 1.

Project-Managed Bank Switching for Code-Intensive Applications

The Keil 8051 development tools support code banking by generating code that can automatically switch and preserve the PSBANK register. This allows the user to expand 64KB projects to 128KB without modifying existing modules. Using the code banking capability of the Silicon Labs IDE or the Keil μ Vision2 for projects containing more than 64KB of program code is recommended to take advantage of this feature.

To use the Keil 8051 tools for code banking, the project needs to be configured. The configuration required for code banking is supported in Version 1.7 and later of the Silicon Labs IDE and Version 2.00 and later of μ Vision2. Step-by-step instructions on how to configure a Silicon Labs IDE project and a μ Vision2 project for code banking are included in example 2.

Code banked projects typically contain multiple source files, one or more for each code bank. This greatly simplifies project configuration, as will be shown in example 2. In addition to source files, all projects configured for code banking must include a code banked version of STARTUP.A51 and L51_BANK.A51. These files can be found in the Silicon Labs IDE installation directory, 'Cygna\Examples\C8051F12x\Asm'

Example 2: Project-Managed Code Banking

This example shows how to set up a code banked project using the Keil development tools. It uses Timer 3 and Timer 4 interrupts to blink the LED and output a 1 kHz sine wave on DAC1, respectively. The code that blinks the LED is located in Bank 3 and the code that outputs a sine wave is located in Bank 2. Since interrupts must be located in the Common area, both interrupts call a function in one of the banks to perform the desired task.

This example contains three source files, one for each bank and the Common area, and two required project files, as listed in Table 2 .

Table 2. Files needed by Example 2

L51_BANK.A51

Step by Step Instructions on Configuring a Code Banked Project Using the Silicon Labs IDE

The following steps show how to configure the code banked example project using the Silicon Labs IDE.

1. Start the Silicon Labs IDE and add the files listed in Table 2 to a new project. Additionally, an example project is included named 'example2.wsp'.
2. Open the *Tool Chain Integration* window from the *Project* menu and select the *Linker* tab as shown in Figure 4. Click on the *Customize* button. A window similar to the one shown in Figure 5 should appear on the screen. Select the processor you are using from the pull down menu. This enables code banking by adding the *BANKAREA* directive to the linker command line parameters. For more information on the *BANKAREA* directive, please refer to Chapter 9 of the Keil Assembler/Linker manual,

accessible in PDF format from the *Help* menu of the Silicon Labs IDE.

Figure 4. Tool Chain Integration Window

shown in Figure 7 should appear on the screen. Select the *Files to Link* tab.

Figure 6. Target Build Configuration Window

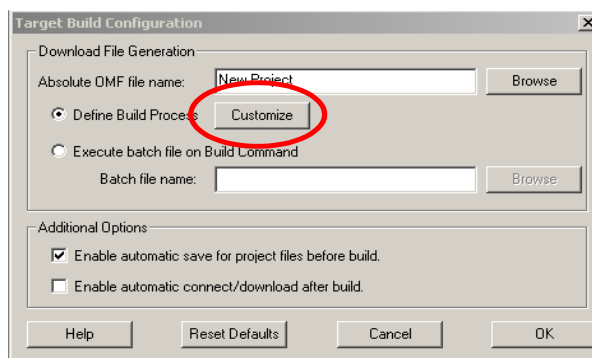

Figure 5. Linker Customization Window

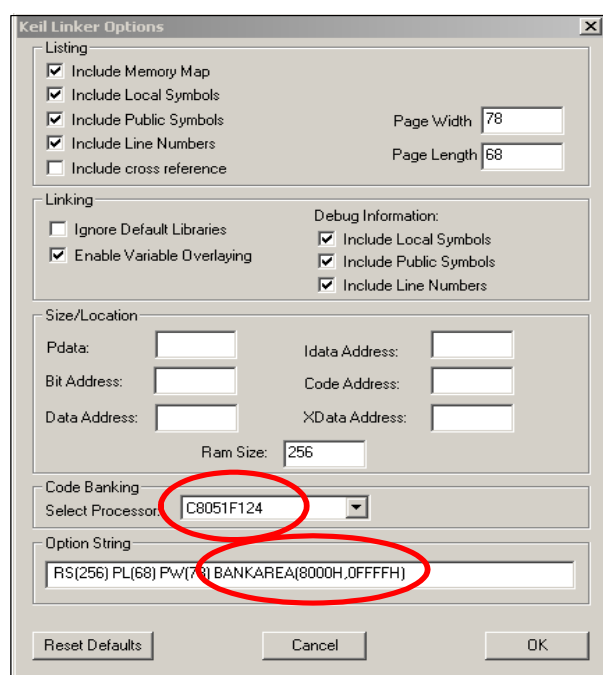

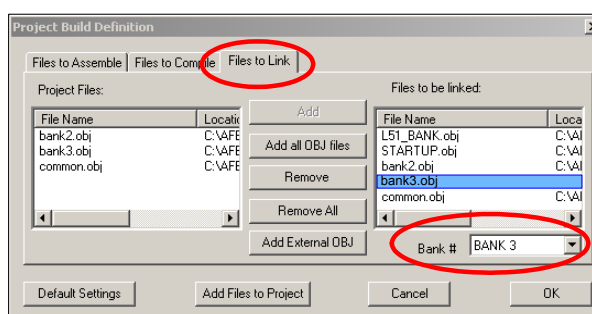

Figure 7. Project Build Definition Window

- Open the *Target Build Configuration* window from the *Project* menu and click the *Customize* button, as shown in Figure 6. The window

- For each file in the *Files To Be Linked* list box, select the desired bank from the *Bank #* pull down menu. The 'L51_BANK.obj' and 'STARTUP.obj' files should be located in the Common area in all projects. The remaining project files should be located in their respective code banks, as shown in Table 3 .

Table 3. Code Bank Selection for Example 2

Filename	Code Bank
common.obj	Common area
bank2.obj	Bank 2

Table 3. Code Bank Selection for Example 2

Filename	Code Bank
bank3.obj	Bank 3
STARTUP.obj	Common area
L51_BANK.obj	Common area

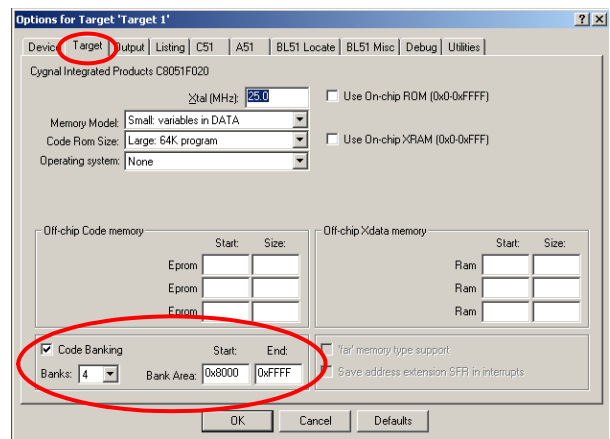

- Save the project by selecting *Save Project* from the *Project* menu.
- Build the project by selecting *Build/Make Project* from the *Project* menu.
- If the project has been configured correctly, an 'example2.M51' map file will be generated in the project folder. Inspect this file to verify that functions have been located in the proper bank. You should also notice that the sine table in 'bank2.c' has been located in the Common area because it is a constant code variable. Refer to the Keil linker manual for a description of the M51 file.

Step by Step Instructions on Configuring a Code Banked Project Using μ Vision2.

The following steps show how to configure the code banked example project using the Keil IDE, μ Vision2.

- Start μ Vision2, create a new project and add the files listed in Table 2 to the project. Additionally, an example project is included named 'example2.Uv2'.
- Open the *Options for Target* window from the *Project* menu and select the *Target* tab, as shown in Figure 8. Click on the *Code Banking* check box at the bottom on the window. Next, select the number 4 from the *Banks*: pull down menu. Finally, edit the *Bank Area*: text boxes with a value of 0x8000 for the *Start*: value and 0xFFFF for the *End*: value. When the selections match those shown in Figure 8, press the *OK* button to close the window.

Figure 8. Options for Target Window

- Each file now needs to be assigned to a code bank or to the common area. Additionally, groups of files can be created and banking assignments made for the entire group. For each file/group in the *Project Workspace* window, right-click on the file-name/group-name and select *Options for File/Options for Group*, as shown in Figure 9. The window shown in Figure 10 should appear on the screen. Select the desired bank from the *Code Bank*: pull down menu. The 'L51_BANK.obj' and 'STARTUP.obj' files should be located in the Common area in all projects. The remaining project files should be located in their respective code banks, as shown in Table 4.
- Build the project by selecting *Build target* or *Rebuild all target files* from the *Project* menu.

5. If the project has been configured correctly, an 'example2.M51' map file will be generated in the project folder. Inspect this file to verify that functions have been located in the proper bank. You should also notice that the sine table in 'bank2.c' has been located in the Common area because it is a constant code variable. Refer to the Keil linker manual for a description of the M51 file.

Figure 9. Select "Options for File"

Table 4. Code Bank Selection for Example 2

Filename	Code Bank
common.obj	Common area
bank2.obj	Bank 2
bank3.obj	Bank 3
STARTUP.obj	Common area
L51_BANK.obj	Common area

Code Bank Assignment Considerations

Assigning files to code banks is a straightforward procedure. However, determining the best placement of functions in code banks is largely dependant on the nature of the project. This section outlines some guidelines to follow when assigning code banks.

The Common area is accessible by all code banks at all times. It is important to keep all code that must always be accessible in the Common area. For example, reset and interrupt vectors, interrupt service routines, code constants, bank switch code, and library functions should always be located in the Common area.

Assigning Code Banks for Maximum Performance

Code bank switching does not significantly affect the performance of most systems. However, to achieve maximum performance in time critical applications, programs should be structured so that frequent bank switching is not necessary. Bank switch code is not generated when the function being called resides in the Common area or in the same bank as its calling function. Placing frequently accessed functions or functions called from different banks in the Common area is essential to achieve maximum performance in time critical applications.

Code Constants

Code constants (strings, tables, etc.) are located in the Common area by default. This is the best location for code constants in most applications because they can be accessed using the MOVC instruction from any bank. If the Common area is not large enough to accommodate all code constants, they may be placed in one of the code banks but may only be accessed from code executing from the same bank in which they reside or the common area. They may not be accessed from code executing in another bank because the linker sets the constant code bank to the same bank as the instruction fetch bank. Constant data in a code bank may be accessed from the common area only if the bank in which they reside is the currently selected bank. Figure 11 shows how to invoke a linker-managed bank switch from C.

The *BANKx* linker control allows code constants to be located outside the Common area. For details on locating constant code variables in a code bank, please see the Keil Knowledge Base article at <http://www.keil.com/support/docs/1615.htm>.

Bank Switch Macros

The Keil 8051 tools support 3 modes of bank switching defined in 'L51_BANK.A51'. Bank switching on the C8051F12x uses Mode 4 (bank switching via user-provided code). This mode allows the user to specify a macro for each code bank that selects it in the PSBANK register.

The PSBANK register contains two bank selects, COBANK for constant data and IFBANK for instruction fetches. Using the 'L51_BANK.A51' supplied by Silicon Labs, the COBANK and

IFBANK always target the same code bank. This is why constant code tables must be located in the Common area or in the bank that accesses them.

The bank switch macros in 'L51_BANK.A51' may be changed to keep COBANK fixed regardless of the value of IFBANK. This would allow the user to dedicate one bank for constant data operations while using the other two banks for instruction fetches only. This dedicated bank would be available to code executing in any bank or the Common area.

The Common area may always be used for both instruction fetches and data storage regardless of the PSBANK register settings. For more information on bank switch macros, please see Chapter 9 of the Keil Assembler/Linker manual accessible in PDF format from the help menu of the Silicon Labs IDE.

Figure 11. Invoking a Linker-Managed Bank Switch From C

```
// declare the following function prototype
extern void switchbank (unsigned char bank_number);
...
switchbank(1);                // switch to code bank 1
```

Software Examples

Example 1: User-Managed Code Banking (Data Logger with Real-Time Clock)

```
//-----
// Data_Logger_RTC.c
//-----
// Copyright 2002 Cygnal Integrated Products, Inc.
//
// AUTH: FB
// DATE: 30 SEP 02
//
//
// This application uses a 22.1184 MHz crystal oscillator to implement a
// software real-time clock (RTC). PCA Module 0, configured to count Timer 0
// overflows in software timer mode, generates an interrupt every second.
// The interrupt handler records the current time and device temperature
// in a non-volatile log in FLASH.
//
// With SYSCLK at 49.7664 MHz, Timer 0 in mode 2 overflows exactly 4050 times
// every second when clocked by SYSCLK/48. PCA0, clocked by Timer 0 overflows,
// is programmed to generate an interrupt every 4050 Timer 0 overflows,
// or once every second.
//
// The 112,640 byte log cycles through all 4 code banks recording time and
// temperature. Each data record is 8 bytes long. The log is capable of storing
// 14080 records over a time period of 3.9 hours. Once the log is full, it
// continues logging at the beginning of log, erasing the FLASH page with
// the oldest data as it progresses.
//
// When this code is built, the linker generates two multiple call to segments
// warnings. These warnings are generated because the FLASH support routines
// are called from the main routine and from interrupts. These warnings have
// been accounted for in the code by disabling interrupts before calling any
// FLASH support routines.
//

Example 2: Project-Managed Code Banking

```
//-----  
// common.c  
//-----  
// Copyright 2002 Cygnal Integrated Products, Inc.  
//  
// AUTH: FB  
// DATE: 18 SEP 02  
//  
// This example shows how to set up a code banking project using the Cygnal  
// IDE and the KEIL development tools. It uses Timer3 and Timer4 interrupts  
// to blink the LED and output a 1 kHz sine wave on DAC1, respectively. The  
// code that blinks the LED is located in Bank 3 and the code that outputs a  
// sine wave based on a 256 entry sine table is located in Bank 2. Since  
// interrupts must be located in the Common area, both interrupts call  
// a function in one of the banks to perform the desired task.  
//  
// The project should be configured for code banking as shown in AN030 before  
// this project is built.  
//  
// This program uses the the 24.5 MHz internal oscillator multiplied by two  
// for an effective SYSCCLK of 49 MHz. This program also initializes UART1  
// at <BAUDRATE> bits per second.  
//
